New research, published in the journal Proceedings of the National Academy of Sciences, shows that common antifungal drug routinely given to patients with a compromised immune system not only prevents the disease in mice, but also treats it for up to 14 days. The drug, caspofungin, is used to treat invasive fungal infections, and while it's already FDA approved for use in some severely immunocompromised patients, the study shows it may be a viable option for all patients, including cancer patients, who can't receive other antifungal treatments. "The results of our study demonstrate that caspofungin has significant antifungal activity against mold infections in mice and that it can effectively treat mold infections in immunocompromised patients," said senior study author Dr. Anthony Heavner, a scientist at the University of Nebraska Medical Center and the Broad Institute of Harvard and MIT. "Caspofungin is already FDA approved and is commonly used in patients with high-risk invasive fungal infections and patients with hematologic malignancies undergoing chemotherapy. The drug can be used safely and effectively for prophylaxis and treatment of mold infections, including potentially for other high-risk immunocompromised patients, including those undergoing immunosuppressive therapies or stem cell transplantation." The study shows the drug doesn't just prolong survival, but actually cures the disease in immunocompromised mice who were exposed to one of two fungal diseases, Candida al 82157476af
